

AT1266 Microprocessor-based Relay Protection Tester

Overview

The ONLLY Relay Protection Tester ONLLY-AT1266-40AH is an advanced and highly reliable testing device specifically designed for testing relay protection systems in electrical networks, substations, and power plants. With a comprehensive set of features, this device is engineered to perform. The microcomputer-based relay protection testing device is a new, miniaturized microcomputer relay protection tester developed on the basis of the “Technical Specifications for Microcomputer-Based Relay Protection Testing Equipment (Draft for Discussion)” issued by the Ministry of Electric Power. The first relays were Electromechanical (EM): machines with moving parts actuated by coils connected to current and voltage sources. These required regular testing, adjustments and maintenance to ensure continued functioning. Relays contained bearings, springs, fixed and movable contacts, rotating on systems, emphasizing the importance of ensuring reliability and security in energy networks. The main focus is on comparing two approaches: traditional methods using conventional devices and modern methods of testing using Hardware-in-Loop (HIL). Traditional methods are simple and intuitive, but. In the author's opinion in order to verify the proper operation of complex multifunctional microprocessor-based protection devices (MPD) at their inspection, start-up after repairs or during periodic tests there is no need to use the actual settings at which the relay is to be operated in a certain. Appropriate relay testing provides a first defense against relay mal-operations and hence improves power grid stability and prevents catastrophic bulk power system failures.
