

# Detecting Optical Attenuation in Single-Core Butterfly Optical Cables

## Overview

The primary tool for measuring attenuation in installed fiber is an Optical Time Domain Reflectometer, or OTDR. this document is the property of JDSU. No part of this book may be reproduced or utilized in any form or means, electronic or mechanical, including photocopying, recording, or by any information storage and retrieval system, without pe n optical fiber to a distant receiver. The OTDR is also commonly used to create a "picture" of fiber optic cable when it is newly installed. It's measured in decibels per kilometer (dB/km), and it determines how far a signal can travel before it becomes too weak to read. A standard single-mode fiber operating at 1550 nm loses. Modal interference can occur in single-mode fiber systems causing signal degradation and potentially lower signal or carrier to noise figures.
