

Is a beam splitter a power divider

Overview

A beam splitter (or beamsplitter, power splitter) is an optical device which can split an incident light beam (e. a laser beam) into two (or sometimes more) beams, which may or may not have the same optical power (radiant flux). It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. Beamsplitters are usually made as a reflective device that splits the beam into exactly 50/50 with half of. Power dividers are an RF microwave accessory constructed with equivalent $50\ \Omega$ resistance at each port. These accessories divide the power of a uniform transmission line equally between ports to enable comparison measurements. Power dividers provide a good impedance match at both the output ports.
