

Optical coupler saturated and conducting

Overview

In the saturation mode of the optocoupler, the emitted light from the diode is high enough to make the phototransistor conducting which results in non-linear collector current I_C followed by a minimum collector emitter voltage V_{CE} . Unlike transformers or capacitors, which can only transfer AC signals across the isolation barrier, optocouplers can. Optocouplers, also known as opto-isolators, are components that transfer electrical signals between two isolated circuits by using infrared light. Transferring signals over a light. Therefore I am limiting the max I_C current to 3. Question is if CTR becomes 300% and I_C will be 3.3 mA then will the opto be saturated or be in linear region?

If it will be in linear region it will give some resistance right?

So my V_{out} won't be properly grounded. They play a very important role in the applications of photonic devices and systems. On the output a wide variety of actuators can be implemented.
