

Principle of Series Beam Splitter

Overview

A beamsplitter is a device designed to either divide or combine light, depending on its intended use. It operates by splitting incoming light into one or two beams, with one or more beams passing through the optical element and one or more beams being redirected at an angle away. A beam splitter or beamsplitter is an optical device that splits a beam of light into a transmitted and a reflected beam. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. a laser beam) into two (or sometimes more) beams, which may or may not have the same optical power (radiant flux). Different types of beam splitters exist, as described in the. Beamsplitters are key instruments deployed across various fields, such as interferometry and optics. However, how they work exactly often remains overlooked.
