

## Why do core switches need backplanes

### Overview

Core switches and routers need maximum throughput with superior signal integrity, and as these systems achieve greater computational power, the backplanes and the number of daughter cards they support become greater in size, number, and complexity. A core switch is a high-capacity, high-performance Layer 3 switch positioned at the physical backbone of an enterprise network. This article outlines six foundational concepts every network engineer should grasp to optimize their use of core switches and enhance overall network performance. Its primary role is high-speed aggregation and forwarding of massive data traffic. Many equipment manufacturers are looking for. We are in the midst of planning a re-cabling of the building and installing new switches. A few different designs have been proposed, and one such design puts our core switches at the heart of our network in such a way that even if one goes down completely, the other can carry on. The idea is that. For core switches, if you want to achieve full-duplex non-blocking, you must meet the minimum standard requirements (backplane bandwidth = port number port rate 2), the higher the backplane bandwidth, the faster the data exchange, the core switch The stronger the data processing capability.
